(57) Abstract

A composition, and methods of enhancing the analgesic potency of morphine and other clinically used bimodally-acting opioid agonists or detoxifying and treating an opiate addict comprising the co-administration of a bimodally-acting opioid agonist which activates inhibitory opioid receptor-mediated functions of neurons in the nociceptive (pain) pathways of the nervous system and an excitatory opioid receptor antagonist which selectively inactivates excitatory opioid agonists.

Methods of enhancing opiate analgesic potency or detoxifying an opiate addict

Statement of Government Interest

5   This invention was made with government support under NIDA research grant number DA 02031. As such, the government has certain rights in the invention.

CROSS-REFERENCE TO RELATED APPLICATIONS

This Application is a Continuation-In-Part of
10   Application Serial No. 07/947,690 filed September 19, 1992, entitled A METHOD OF IDENTIFICATION OF NON-ADDICTIVE OPIOID ANALGESICS AND THE USE OF SAID ANALGESICS FOR TREATMENT OF OPIOID ADDICTION.

FIELD OF THE INVENTION

15   This invention relates to a method of enhancing the analgesic (inhibitory) effects of bimodally-acting opioid agonists, including morphine and other clinically used opioid analgesics, while at the same time attenuating anti-analgesic effects, physical dependence, tolerance, hyperexcitability,
20   hyperalgesia, and other undesirable (excitatory) side-effects typically caused by chronic use of bimodally-acting opioid agonists. As used herein, the term "opioid" refers to compounds which bind to specific opioid receptors and have agonist (activation) or antagonist (inactivation) effects at
25   these receptors, such as opioid alkaloids, including the

agonist morphine and the antagonist naloxone, and opioid peptides, including enkephalins and dynorphins. As used herein, the term "opiate" refers to drugs derived from opium or related analogs.

5   In the instant invention, a selective excitatory opioid receptor antagonist is combined with a reduced dose of a bimodally-acting opioid agonist so as to elicit the desired degree of analgesia (inhibitory effects) and attenuate undesired side-effects (excitatory effects). Opioid analgesia

10 results from activation (by opioid agonists) of inhibitory opioid receptors on neurons in the nociceptive (pain) pathways of the peripheral and central nervous systems. The undesirable side-effects, including anti-analgesic actions, the development of physical dependence, some types of tolerance,

15 hyperexcitability and hyperalgesia, result from sustained activation (by bimodally-acting opioid agonists) of excitatory opioid receptors on neurons in the nociceptive (pain) pathways of the peripheral and central nervous systems. The administration of selective excitatory receptor antagonists

20 together with bimodally-acting opioid agonists enhances analgesic effects caused by said opioids and attenuates the development of physical dependence, tolerance and other undesirable side-effects which are also caused by said opioids. In addition, combined use of the opioid receptor

25 antagonists and agonists of the invention can be used for more effective detoxification and treatment of opiate addicts.

-2-

BACKGROUND OF THE INVENTION

Morphine or other bimodally-acting opioid agonists are administered to relieve severe pain due to the fact that they have analgesic effects mediated by their activation of inhibitory opioid receptors on nociceptive neurons (see North, _Trends Neurosci._, Vol. 9, pp. 114-117 (1986) and Crain and Shen, _Trends Pharmacol. Sci._, Vol. 11, pp. 77-81 (1990)). However, bimodally-acting opioid agonists also activate opioid excitatory receptors on nociceptive neurons, which attenuates the analgesic potency of said opioids and results in the development of physical dependence thereon and increased tolerance thereto (see Shen and Crain, _Brain Res._, Vol. 597, pp. 74-83 (1992)), as well as hyperexcitability, hyperalgesia and other undesirable (excitatory) side-effects. As a result, a long-standing need has existed to develop a method of both enhancing the analgesic (inhibitory) effects of bimodally-acting opioid agonists and limiting the undesirable (excitatory) side-effects caused by such opioid agonists.

The parent Patent Application for the instant invention, Serial No. 07/947,690, relates to a specific group of opioid agonists for use as low/non-addictive analgesics and for the treatment of opioid addiction. In the parent Application, it is stated that this group of opioid agonists (which includes etorphine and dihydroetorphine) bind to and activate inhibitory but not excitatory opioid receptors. (In

-3-

contrast, morphine and most other opioid alkaloids and peptides elicit bimodal effects by binding to and activating both excitatory and inhibitory opioid receptors.)

To date, no method has been discovered or developed whereby two opioid compounds are administered, one of which binds to and activates inhibitory opioid receptors to cause analgesia and the other of which binds to and inactivates excitatory opioid receptors so as to attenuate undesirable side-effects caused by the administration of bimodally-acting opioid agonists while simultaneously enhancing the analgesic effects of said bimodally-acting opioid agonists.

It is therefore an object of this invention to provide a method of enhancing the analgesic potency of morphine and other bimodally-acting opioid agonists by blocking their anti-analgesic side-effects.

It is a further object of this invention to provide a method of attenuating physical dependence, tolerance, hyperexcitability, hyperalgesia and other undesirable side-effects caused by the chronic administration of bimodally-acting opioid agonists.

It is another object of this invention to provide a method for detoxifying and treating opiate addicts utilizing excitatory opioid receptor antagonists.

It is yet another object of this invention to provide a composition which enhances the analgesic effects of

-4-

bimodally-acting opioid agonists while simultaneously attenuating undesirable side-effects caused by said opioid agonists, including physical dependence, tolerance, hyperexcitability and hyperalgesia.

5   It is still a further object of this invention to provide a composition which is useful for detoxification and treatment of opiate addicts.

SUMMARY OF THE INVENTION

          This invention is directed to a method of selectively

10   enhancing the potency of morphine and other conventional bimodally-acting opioid agonists and simultaneously attenuating undesirable side-effects, including physical dependence, caused by the chronic administration of said opioid agonists. Morphine and other bimodally-acting (inhibitory/excitatory)

15   opioid agonists bind to and activate inhibitory and excitatory opioid receptors on nociceptive neurons mediating pain. Activation of inhibitory receptors by said agonists causes analgesia. Activation of excitatory receptors by said agonists results in anti-analgesic effects, development of physical

20   dependence, tolerance, hyperexcitability, hyperalgesia and other undesirable side-effects. The co-administration of an opioid antagonist which binds to and inactivates excitatory opioid receptors results in the blocking of excitatory anti-analgesic side-effects of said opioid agonists on these

-5-

neurons, thereby resulting in enhanced analgesic potency which permits the use of lower doses of morphine or other conventional opioid analgesics.

The excitatory opioid receptor antagonists of the
5   invention include etorphine, dihydroetorphine, diprenorphine and similarly acting opioid alkaloids and opioid peptides. The opioid agonists of the invention include morphine or other bimodally-acting (inhibitory/excitatory) opioid alkaloids or opioid peptides that are in clinical use as analgesics,
10   including codeine, fentanyl analogs and endorphins.

In addition, combinations of an excitatory opioid receptor antagonist and morphine or another conventional bimodally-acting opioid analgesic can be used to detoxify and treat opiate addicts.

15   BRIEF DESCRIPTION OF THE DRAWINGS

The above brief description, as well as further objects and features of the present invention, will be more fully understood by reference to the following detailed description of the presently preferred, albeit illustrative,
20   embodiments of the present invention when taken in conjunction with the accompanying drawings wherein:

Figure 1 represents the direct inhibitory effect of etorphine on the action potential duration (APD) of sensory neurons and the blocking effect of etorphine on the excitatory

-6-

response (APD prolongation) elicited by morphine. Acute application of low (pM-nM) concentrations of etorphine to naive dorsal root ganglion (DRG) neurons elicits dose-dependent, naloxone-reversible inhibitory shortening of the APD. In contrast, morphine and other bimodally-acting opioid agonists elicit excitatory APD prolongation at these low concentrations which can be selectively blocked by <pM levels of etorphine;

Figure 2 represents dose-response curves of different opioids, showing that etorphine and dihydroetorphine elicit only inhibitory dose-dependent shortening of the APD of DRG neurons at <u>all</u> concentrations tested (fM-μM). In contrast, dynorphin A (as well as morphine and other bimodally-acting opioids) elicits dose-dependent excitatory APD prolongation at low concentrations (fM-nM) and requires much higher concentrations (about 0.1-1 μM) to shorten the APD, thereby resulting in a bell-shaped dose-response curve;

Figure 3 is comprised of Figure 3A and 3B, and represents the selective blocking of excitatory APD-prolonging effects elicited by morphine in DRG neurons by co-administration of a low (pM) concentration of diprenorphine, thereby unmasking potent dose-dependent inhibitory APD shortening by low concentrations of morphine;

Figure 4 represents the blocking of supersensitive excitatory APD-prolonging effect of DRG neurons after chronic morphine exposure by the excitatory opioid receptor antagonist, etorphine. After chronic exposure to morphine or other

-7-

bimodally-acting opioids, DRG neurons become supersensitive to
the excitatory APD prolonging effects of these opioids, whereas
etorphine becomes even more effective in eliciting inhibitory
shortening of the APD of the same DRG neurons when tested in

5   the presence of the chronic opioid. The apparent enhancement
in inhibitory potency of etorphine on chronic morphine-treated
neurons is due to the unmasking of inhibitory APD shortening
effects of morphine following etorphine-antagonist action at
excitatory opioid receptors;

10   Figure 5 represents the blocking effect of etorphine
on naloxone-precipitated excitatory APD prolongation of DRG
neurons after chronic exposure to morphine or other
bimodally-acting opioids. Acute application of low
concentrations of etorphine can dose-dependently block the

15   excitatory APD-prolonging effects of naloxone on these
supersensitive DRG neurons; and

          Figure 6 represents the ability of etorphine to elicit
sustained inhibitory effects without causing supersensitivity
and tolerance in DRG neurons after chronic treatment. Chronic

20   exposure of etorphine (nM) to DRG neurons did not elicit
supersensitive excitatory responses (APD prolongation) to low
test concentrations of dynorphin A (1-13) and naloxone nor did
these cells develop tolerance to the inhibitory effects of
etorphine or other opioid agonists.

25

-8-

DETAILED DESCRIPTION OF THE INVENTION

This invention is directed to a method of selectively enhancing the analgesic effect caused by the administration of a bimodally-acting opioid agonist and simultaneously
5   attenuating undesirable side-effects caused by the chronic administration of said bimodally-acting opioid agonists. This is performed by simultaneously inactivating excitatory opioid receptor-mediated functions of neurons in the nociceptive (pain) pathways and activating inhibitory opioid receptor-
10 mediated functions of nociceptive neurons. A bimodally-acting opioid agonist and an excitatory opioid receptor antagonist are co-administered. The bimodally-acting opioid agonist binds to inhibitory receptors on nociceptive neurons so as to activate inhibitory opioid receptor-mediated functions, including
15 analgesia, and concomitantly activates excitatory opioid receptors on nociceptive neurons. The excitatory opioid receptor antagonist binds to excitatory receptors on said neurons and thereby inactivates excitatory opioid receptor-mediated functions, including anti-analgesic effects,
20 physical dependence and tolerance to the opioid agonist, hyperexcitability and hyperalgesia. In addition, this invention is directed to the use of said excitatory opioid receptor antagonists and opioid agonists to detoxify and treat opiate addicts. Further, this invention is directed to a
25 composition comprising an excitatory opioid receptor antagonist and a bimodally-acting opioid agonist.

-9-

The inventors have discovered that certain compounds act as excitatory opioid receptor antagonists, that is, they bind to and inactivate excitatory opioid receptors on neurons in the pain pathways. The excitatory opioid receptor antagonists of the invention are preferably selected from the group consisting of etorphine, dihydroetorphine and diprenorphine. The opioid receptor antagonists of the invention inactivate mu, delta, kappa and other subtypes of excitatory opioid receptors. They may have varying structures. For example, etorphine and dihydroetorphine have very similar chemical structures and are considered to be potent analgesics which selectively activate inhibitory but not excitatory opioid receptors (see Shen and Crain, Regulatory Peptides, in press (1993)). In contrast, diprenorphine has a somewhat different chemical structure than etorphine and dihydroetorphine and has been previously considered to act as a universal opioid receptor antagonist by inactivating all types of inhibitory and excitatory opioid receptors (see Shen and Crain, Brain Res., Vol. 491, pp. 227-242 (1989)). Nevertheless, these three compounds are all capable of selectively binding to and inactivating excitatory opioid receptors on nociceptive neurons when administered at low concentrations.

The bimodally-acting opioid agonists of this invention preferably include morphine, codeine, fentanyl analogs, endorphins, and other opioid alkaloids and opioid peptides.

Typically, the opioid agonists of the invention are mu, delta, kappa or epsilon opioid receptor agonists, and are capable of binding to inhibitory opioid receptors on neurons in the pain pathway. When these bimodally-acting agonists bind to

5   inhibitory opioid receptors, they thereby activate inhibitory opioid receptor-mediated functions, including analgesia.

As discussed below, the inventors have discovered that certain compounds (the excitatory opioid receptor antagonists of the invention), when co-administered with bimodally-acting

10   opioid agonists, are capable at very low dosages of enhancing the analgesic effects of the bimodally-acting opioid agonists at least 10-1000 fold by inactivating excitatory anti-analgesic side-effects of said agonists. In addition, the excitatory opioid receptor antagonists of the invention inactivate other

15   excitatory receptor-mediated functions, and thereby reduce the undesirable side-effects caused by said opioid agonists, including development of physical dependence, tolerance to the opioid agonists, hyperexcitability and hyperalgesia. In addition, the excitatory opioid receptor antagonists of the

20   invention may be administered to detoxify and treat opiate addicts.

Ordinarily, bimodally-acting opioid agonists are administered clinically in pill form and are administered in milligram dosages. By co-administering bimodally-acting opioid

25   agonists with the excitatory opioid receptor antagonists of the

-11-

invention, it is possible to achieve an analgesic effect with 10-1000 times lower doses of the bimodally-acting opioid agonist than when said opioid agonist is administered alone. This is because the excitatory opioid receptor antagonists of

5   the invention enhance the analgesic effects of the bimodally-acting opioid agonists by attenuating the anti-analgesic excitatory side-effects of said opioid agonists. Hence, bimodally-acting opioid agonists which are administered with the excitatory opioid receptor antagonists of

10   the invention are administered in an amount 10-1000 times less than the amount of that bimodally-acting opioid agonist which has typically been administered for analgesia.

     According to the present invention, the dose of excitatory opioid receptor antagonist to be administered is

15   10-1000 times less than the dose of bimodally-acting opioid agonist to be administered, for example, < 1 microgram of said antagonist together with 10-100 micrograms of said agonist. These estimates of dosages are based on studies of neurons in culture. The excitatory opioid receptor antagonists, as well

20   as the opioid agonists, can be administered sublingually, intramuscularly, subcutaneously or intraveneously.

     The co-administration of the opioid agonists and excitatory opioid receptor antagonists of the invention simultaneously activates inhibitory functions of nociceptive

25   neurons in the pain pathway and inactivates excitatory

-12-

functions of the same or other nociceptive neurons. In order to demonstrate this, electrophysiologic studies on the effects of opioids on mouse sensory dorsal root ganglion neurons in tissue cultures were performed. It is shown below that this

5   bimodal modulation is mediated by activating putative excitatory opioid receptors in addition to previously characterized inhibitory opioid receptors on sensory neurons.

It is shown that at low pM-nM concentrations, nearly all opioids, including morphine, enkephalins, dynorphins,

10 endorphins and specific mu, delta and kappa opioid agonists, elicit naloxone-reversible dose-dependent excitatory effects manifested by prolongation of the calcium-dependent component of the action potential duration (APD) of dorsal root ganglia (DRG) neurons. In contrast, the same opioids generally elicit

15 inhibitory APD shortening effects when applied at higher concentrations (0.1-1 μM).

The excitatory opioid effects on sensory neurons have been shown to be mediated by opioid receptors that are coupled via a cholera-toxin-sensitive stimulatory GTP-binding protein,

20 Gs, to adenylate cyclase/cyclic AMP/protein kinase A-dependent ionic conductances that prolong the APD (resembling, for example, beta-adrenergic receptors). (See Crain and Shen, Trends Pharmacol. Sci., Vol. 11, pp. 77-81 (1990)). On the other hand, inhibitory opioid effects are mediated by opioid

25 receptors that are coupled via pertussis toxin-sensitive

inhibitory G proteins: Gi to the adenylate cyclase/cyclic AMP system and Go to ionic conductances that shorten the APD (resembling, for example, $alpha_2$-adrenergic receptors). Shortening by opioids of the action potential of primary sensory neurons has generally been considered to be a useful model of their inhibition of calcium influx and transmitter release at presynaptic terminals in the dorsal spinal cord, thereby accounting for opioid-induced analgesia in vivo. (See North, Trends Neurosci., Vol. 9, pp. 114-117 (1986) and Crain and Shen, Trends Pharmacol. Sci., Vol. 11, pp. 77-81 (1990)). Similarly, the delayed repolarization associated with the observed opioid-induced prolongation of action potential has been interpreted as evidence of excitatory effects of opioids on sensory neurons that may result in enhanced calcium influx and transmitter release at presynaptic terminals. This could account for some types of hyperalgesia and hyperexcitatory states elicited by opioids in vivo (see Crain and Shen, Trends Pharmacol. Sci., Vol. 11, pp. 77-81 (1990) and Shen and Crain, Brain Res., Vol. 491, pp. 227-242 (1989).

Chronic treatment of DRG neurons with typical bimodally-acting (excitatory/inhibitory) opioids (e.g., 1 µM D-ala^2-D-leu^5 enkephalin (DADLE) or morphine for 1 week) results in tolerance to the usual inhibitory APD-shortening effects of high concentrations of these opioids and supersensitivity to the excitatory APD-prolonging effects of

-14-

these opioid agonists, as well as the opioid antagonist, naloxone (see Crain and Shen, Brain Res., Vol. 575, pp. 13-24 (1992) and Shen and Crain, Brain Res., Vol. 597, pp. 74-83 (1992)). It has been suggested that the latter electrophysiologic effects and related biochemical adaptations are cellular manifestations of physical dependence that may underlie some aspects of opiate addiction (see Shen and Crain, Brain Res., Vol. 597, pp. 74-83 (1992) and Terwilliger et al., Brain Res., Vol. 548, pp. 100-110 (1991)).

In contrast to bimodally-acting opioids, it has been discovered by the inventors that the opioid alkaloids, etorphine (see Bentley and Hardy, Proc. Chem. Soc., pp. 220 (1963)) and dihydroetorphine (see Bentley and Hardy, J. Amer. Chem. Soc., Vol. 89, pp. 3281-3286 (1967)) uniquely elicit dose-dependent, naloxone-reversible inhibitory effects on sensory neurons in DRG-spinal cord explants, even at concentrations as low as 1 pM, and show no excitatory effects at lower concentrations (see Shen and Crain, Regulatory Peptides, in press (1993)). In addition, these potent inhibitory opioid receptor agonists also display unexpected antagonist effects at excitatory opioid receptors on DRG neurons. Acute pretreatment of DRG neurons with etorphine or dihydroetorphine, at low concentrations (<pM) which do not alter the APD, block the excitatory APD-prolonging effects of morphine and other bimodally-acting opioids and unmask

-15-

inhibitory APD-shortening effects which normally require much higher concentrations. The potent inhibitory effect of etorphine and dihydroetorphine may be due to their selective activation of inhibitory opioid receptor-mediated functions while simultaneously inactivating excitatory opioid receptor-mediated functions in sensory neurons. In contrast, bimodally-acting opioids activate high-affinity excitatory as well as inhibitory opioid receptors on DRG neurons, thereby decreasing the net inhibitory effectiveness of these agonists, resembling the attenuation of the inhibitory potency of systemic morphine by the "anti-analgesic" (excitatory) effect of dynorphin A release in spinal cord in mice (see Fujimoto et al., Neuropharmacol., Vol. 29, pp. 609-617, (1990)).

Acute application of pM-nM etorphine or dihydroetorphine to chronic μM morphine-treated DRG neurons elicited marked APD shortening (as in naive cells) even when added during naloxone-precipitated APD-prolongation in these sensitized cells, whereas 10 μM morphine or DADLE were ineffective and in contrast elicited a marked APD prolongation. These potent inhibitory effects of etorphine and dihydroetorphine on the action potential of chronic morphine-treated sensory neurons show remarkable mimicry of the rapid DHE-induced blockade of naloxone-evoked withdrawal syndromes in opiate-addicted animals and humans (see Wang et al., Chinese J. Pharmacol. Toxicol., Vol. 6, pp. 36-40 (1992)

and Qin, Chinese J. Pharmacol. Toxicol., Vol. 6 (1992)) and the absence of cross-tolerance to etorphine in chronic morphine-treated mice even when the analgesic ED50 for morphine had increased 15-fold (see Lange et al., Toxicol. Applied Pharmacol., Vol. 54, pp. 177-186 (1980)). Furthermore, chronic treatment of DRG neurons with 10 nM etorphine for >1 week did not result in opioid excitatory supersensitivity, i.e., APD prolongation following acute application of fM dynorphin A (1-13) or nM naloxone, nor tolerance to opioid inhibitory effects, all of which occur after chronic treatment with bimodally-acting opioids, e.g., DADLE or morphine (see Crain and Shen, Brain Res., Vol. 575, pp. 13-24 (1992) and Shen and Crain, Brain Res., Vol. 597, pp. 74-83 (1992)).

In vitro studies on sensory neurons suggested that an opioid which can selectively activate inhibitory, and inactivate excitatory, opioid receptor functions would be a unique analgesic in vivo with high potency, low dependence liability, and useful for treatment of opiate addicts.

Example 1

Etorphine And Dihydroetorphine Act As Potent Selective Antagonists At Excitatory Opioid Receptors On DRG Neurons Thereby Enhancing Inhibitory Effects Of Bimodally-Acting Opioid Agonists

Methods: The experiments described herein were carried out on dorsal root ganglion (DRG) neurons in

organotypic explants of spinal cord with attached DRGs from 13-day-old fetal mice after 3 to 5 weeks of maturation in culture. The DRG-cord explants were grown on collagen-coated coverslips in Maximow depression-slide chambers. The culture

5   medium consisted of 65% Eagle's minimal essential medium, 25% fetal bovine serum, 10% chick embryo extract, 2 mM glutamine and 0.6% glucose. During the first week _in_ _vitro_ the medium was supplemented with nerve growth factor (NGF-7S) at a concentration of about 0.5 µg/ml, to enhance survival and

10   growth of the fetal mouse DRG neurons.

In order to perform electrophysiologic procedures, the culture coverslip was transferred to a recording chamber containing about 1 ml of Hanks' balanced salt solution (BSS). The bath solution was supplemented with 4 mM Ca^{2+} and 5 mM

15   Ba^{2+} (i.e., Ca,Ba/BSS) to provide a prominent baseline response for pharmacological tests. Intracellular recordings were obtained from DRG perikarya selected at random within the ganglion. The micropipettes were filled with 3 M KCl (having a resistance of about 60-100 megohms) and were connected via a

20   chloridized silver wire to a neutralized input capacity preamplifier (Axoclamp 2A) for current-clamp recording. After impalement of a DRG neuron, brief (2 msec) depolarizing current pulses were applied via the recording electrode to evoke action potentials at a frequency of 0.1 Hz. Recordings of the action

25   potentials were stored on a floppy disc using the P-clamp

-18-

program (Axon Instruments) in a microcomputer (IBM AT-compatible).

Drugs were applied by bath perfusion with a manually operated, push-pull syringe system at a rate of 2-3 ml/min.

5   Perfusion of test agents was begun after the action potential and the resting potential of the neuron reached a stable condition during >4-minute pretest periods in control Ca, Ba/BSS. Opioid-mediated changes in the APD were considered significant if the APD alteration was >10% of the control value

10   for the same cell and was maintained for the entire test period of 5 minutes. The APD was measured as the time between the peak of the APD and the inflection point on the repolarizing phase. The following drugs were used: etorphine, diprenorphine and morphine (gifts from Dr. Eric Simon);

15   dihydroetorphine (gift from Dr. B.-Y. Qin, China); naloxone (Endo Labs); DADLE, dynorphin and other opioid peptides (Sigma).

Opioid alkaloids and peptides were generally prepared as 1 mM solutions in H_2O and then carefully diluted with BSS to the desired concentrations, systematically discarding

20   pipette tips after each successive 1-10 or 1-100 dilution step to ensure accuracy of extremely low (fM-pM) concentrations.

Results: The opioid responsiveness of DRG neurons was analyzed by measuring the opioid-induced alterations in the APD of DRG perikarya. A total of 64 DRG neurons (from 23 DRG-cord

25   explants) were studied for sensitivity to progressive increases

in the concentration of etorphine (n=30) or dihydroetorphine
(n=38). Etorphine rapidly and dose-dependently shortened the
APD in progressively larger fractions of DRG cells at
concentrations from 1 fM (30% of cells; n=26) to 1 μM (80% of

5   cells; n=16) (see Figures 1 and 2).

Figure 1 shows that acute application of low (pM-nM)
concentrations of etorphine to naive DRG neurons elicits
dose-dependent, naloxone-reversible inhibitory shortening of
the action potential duration (APD). In contrast, dynorphin

10   (and many other bimodally-acting opioid agonists, e.g.,
morphine, DADLE) elicit excitatory APD prolongation at these
low concentrations (see Figure 2), which can be selectively
blocked by < pM levels of etorphine or diprenorphine (see
Figure 3). Figure 1A record 1 shows the action potential (AP)

15   generated by a DRG neuron in balanced salt solution containing
5 mM Ca^{2+} and 5 mM Ba^{2+} (BSS). AP response in this record
(and in all records below) is evoked by a brief (2 msec)
intracellular depolarizing current pulse. Figure 1A records
2-5 show that APD is not altered by bath perfusion with 1 fM

20   etorphine (Et) but is progressively shortened in 1 pM, 1 nM and
1 μM concentrations (5 minute test periods). Figure 1A
record 6 shows that APD returns to control value after transfer
to BSS (9 minute test). Figure 1B records 1 and 2 show that
APD of another DRG neuron is shortened by application of 1 nM

25   etorphine (2 minute test). Figure 1B record 3 shows that APD

returns to control value after transfer to 10 nM naloxone
(NLX). Figure 1B records 4 and 5 show that APD is no longer
shortened by 1 nM or even 1 μM etorphine when co-perfused
with 10 nM naloxone (5 minute test periods). Figure 1C records

5   1 and 2 show that APD of another DRG neuron is prolonged by
application of 3 nM morphine. Figure 1C record 3 shows that
APD returns to control value by 5 minutes after washout.
Figure 1C record 4 shows that application of 1 pM etorphine
does not alter the APD. Figure 1C record 5 shows that APD is

10   no longer prolonged by 3 nM morphine when co-perfused with 1 pM
etorphine and instead is markedly shortened to a degree which
would require a much higher morphine concentration in the
absence of etorphine. Similar results were obtained by
pretreatment with 1 pM diprenorphine (see Figure 3). Records

15   in this and subsequent Figures are from DRG neurons in
organotypic DRG-spinal cord explants maintained for 3-4 weeks
in culture.

Figure 2 shows dose-response curves demonstrating that
etorphine (Et) (□) and dihydroetorphine (DHE) (◇) elicit

20   only inhibitory dose-dependent shortening of the APD of DRG
neurons at all concentrations tested (fM-μM). In contrast,
dynorphin A (1-13) (Dyn) (X) (as well as morphine and other
bimodally-acting opioids) elicits dose-dependent excitatory APD
prolongation at low concentrations (fM-nM) and generally

25   requires much higher concentrations (about 0.1-1 μM) to

shorten the APD, thereby resulting in a bell-shaped dose-response curve. Data were obtained from 11 neurons for the etorphine tests, 13 for the DHE tests and 35 for the dynorphin tests; 5, 8 and 9 neurons were tested (as in Figure 1) with all four concentrations of etorphine, DHE and dynorphin, respectively (from fM to μM). For sequential dose-response data on the same neuron, the lowest concentrations (e.g., 1 fM) were applied first.

Dihydroetorphine was even more effective (n=38; Figure 2). Naloxone (10 nM) prevented the etorphine- and dihydroetorphine-induced APD shortening which was previously elicited in the same cells (n=12; Figure 1B). These potent inhibitory effects of etorphine and dihydroetorphine on DRG neurons at low concentrations are in sharp contrast to the excitatory APD-prolonging effects observed in similar tests with morphine and a wide variety of mu, delta and kappa opioids. None of the DRG neurons tested with different concentrations of etorphine or dihydroetorphine showed prominent APD prolongation.

The absence of excitatory APD-prolonging effects of etorphine and dihydroetorphine on DRG neurons could be due to low binding affinity of these opioid agonists to excitatory opioid receptors. Alternatively, these opioids might bind strongly to excitatory receptors, but fail to activate them, thereby functioning as antagonists. In order to distinguish

-22-

between these two modes of action, DRG neurons were pretreated
with etorphine at low concentrations (fM-pM) that evoked little
or no alteration of the APD. Subsequent addition of nM
concentrations of morphine, DAGO, DADLE or dynorphin to

5   etorphine-treated cells no longer evoked the usual APD
prolongation observed in the same cells prior to exposure to
etorphine (n=11; see Figure 1C). This etorphine-induced
blockade of opioid excitatory effects on DRG neurons was often
effective for periods up to 0.5-2 hours after washout (n=4).

10   These results demonstrate that etorphine, which has
been considered to be a "universal" agonist at mu, delta and
kappa opioid receptors (see Magnan et al.,
Naunyn-Schmiedleberg's Arch. Pharmacol., Vol. 319, pp. 197-205
(1982)), has potent antagonist actions at mu, delta and kappa

15   excitatory opioid receptors on DRG neurons, in addition to its
well-known agonist effects at inhibitory opioid receptors.
Pretreatment with dihydroetorphine (fM-pM) showed similar
antagonist action at excitatory opioid receptor mediating nM
opioid-induced APD prolongation (n=2). Furthermore, after

20   selective blockade of opioid excitatory APD-prolonging effects
by pretreating DRG neurons with low concentrations of etorphine
(fM-pM), which showed little or no alteration of the APD, fM-nM
levels of bimodally-acting opioids now showed potent inhibitory
APD-shortening effects (5 out of 9 cells) (see Figure 1C and

25   Figure 3). This is presumably due to unmasking of inhibitory

-23-

opioid receptor-mediated functions in these cells after selective blockade of their excitatory opioid receptor functions by etorphine.

Example 2

Diprenorphine At Low Concentration Also Shows Potent Selective Antagonist Action At Excitatory Opioid Receptors

Drug tests: Mouse DRG-cord explants, grown for >3 weeks as described in Example 1, were tested with the opioid antagonist, diprenorphine. Electrophysiological recordings were made as in Example 1.

Results: The "universal" opioid receptor antagonist, diprenorphine was previously shown to block, at nM concentrations, both inhibitory APD shortening of DRG neurons by μM opioid agonists as well as excitatory APD prolongation by nM opioids. Tests at lower concentrations have revealed that pM diprenorphine acts selectively as an antagonist at mu, delta and kappa excitatory opioid receptors, comparable to the antagonist effects of pM etorphine and dihydroetorphine. In the presence of pM diprenorphine, morphine (n=7) and DAGO (n=7) no longer elicited APD prolongation at low (pM-nM) concentrations (see Figure 3A). Instead, they showed progressive dose-dependent APD shortening throughout the entire range of concentrations from fM to μM (see Figure 3B), comparable to the dose-response curves for etorphine and

-24-

dihydroetorphine (see Figure 2 and Figure 1C). This unmasking of inhibitory opioid receptor-mediated APD-shortening effects by pM diprenorphine occurred even in the presence of 10^6-fold higher concentrations of morphine (see Figure 3A, records 11

5   vs. 5).

Figure 3 shows that excitatory APD-prolonging effects elicited by morphine in DRG neurons are selectively blocked by co-administration of a low (pM) concentration of diprenorphine, thereby unmasking potent dose-dependent inhibitory APD

10   shortening by low concentrations of morphine. Figure 3A records 1-4 show that APD of a DRG neuron is progressively prolonged by sequential bath perfusions with 3 fM, 3 pM and 3 nM morphine (Mor). Figure 3A record 5 shows that APD of this cell is only slightly shortened after increasing morphine

15   concentration to 3 μM. Figure 3A records 6 and 7 show that after transfer to BSS, the APD is slightly shortened during pretreatment for 17 minutes with 1 pM diprenorphine (DPN). Figure 3A records 8-11 show that after the APD reached a stable value in DPN, sequential applications of 3 fM, 3 pM, 3 nM and

20   3 μM Mor progressively shorten the APD, in contrast to the marked APD prolongation evoked by these same concentrations of Mor in the absence of DPN (see also Figure 1C). Figure 3B dose-response curves demonstrate similar unmasking by 1 pM DPN of potent dose-dependent inhibitory APD shortening by morphine

25   (X) in a group of DRG neurons (n=7), all of which showed only

-25-

excitatory APD prolongation responses when tested prior to introduction of DPN (X). Note that the inhibitory potency of morphine in the presence of pM DPN becomes comparable to that of etorphine and diprenorphine (see Figure 2).

5   Example 3

Enhanced Inhibitory Effect of Etorphine and Dihydroetorphine On Chronic Opioid-Treated Sensory Neurons Which Become Supersensitive To Opioid Excitatory Effects

        Drug tests: Mouse DRG-cord explants, grown for >3
10 weeks as described in Example 1, were chronically exposed to the bimodally-acting (excitatory/inhibitory) delta/mu opioid agonist, DADLE (1 µM) or morphine (1 µM) for 1 week or longer and tested acutely with etorphine or dihydroetorphine. Electrophysiological recordings were made as in Example 1.

15   Results: Acute application of fM etorphine to chronic µM DADLE- or morphine-treated DRG neurons (for > 1 week) was still effective in shortening the APD in 30% of the treated neurons (n=23) when tested in the presence of µM DADLE or morphine (see Figure 4). Furthermore, pM levels of etorphine
20 shortened the APD in 76% of the cells tested (n=21).

        Figure 4 shows that after chronic exposure to morphine (Mor), or other bimodally-acting opioids, DRG neurons become supersensitive to the excitatory APD-prolonging effects of these opioids, whereas etorphine (Et) becomes even more
25

effective in eliciting inhibitory shortening of the APD of the same DRG neurons when tested acutely in the presence of the chronic opioid. Dose-response curves show that after chronic treatment of DRG neurons with 3 μM Mor for 2-3 weeks in culture, the magnitude of APD shortening elicited by acute application of Et ($\Diamond$) is markedly enhanced at all test concentrations (fM-μM); see typical records in Inset); thereby shifting the dose-response curve sharply to the left, as compared to data obtained from naive DRG neurons ($\Box$). In contrast, after washout of the chronic morphine with BSS, retests of sequentially increasing concentrations of Et from fM to μM result in less prominent APD shortening (X), comparable to, or even weaker than, Et effects on naive cells ($\Box$). These results suggest that the apparent enhancement in inhibitory potency of Et on chronic Mor-treated neurons is actually due to unmasking of inhibitory APD-shortening effects of chronic Mor following Et-antagonist action at excitatory opioid receptors, as occurs in tests on naive DRG cells (see Figure 1C). As shown in the inset, Figure 4 record 1 shows AP generated by a DRG neuron treated for 3 weeks in culture with 3 μM Mor and then tested in BSS in the presence of the chronic Mor. Figure 4 record 2 shows that 1 fM Et does not alter the APD in the presence of 3 μM Mor. Figure 4 records 3-5 show that sequential increases in the concentration of Et from 1 pM to 1 μM progressively shortens the APD in the

-27-

presence of 3 μM Mor (whereas dynorphin dose-dependently prolonged the APD of the same chronic opioid-treated cell -- not shown; see Figure 2).

In contrast, morphine, DADLE and other chronic
5   bimodally-acting opioid-treated DRG neurons showed. supersensitive excitatory APD-prolonging effects when tested with low (fM-pM) concentrations of dynorphin (1-13) before (n=13) or after (n=6) washout of the chronic DADLE or morphine. The effectiveness of etorphine in eliciting
10   inhibitory APD-shortening in chronic opioid-treated DRG neurons appeared to be significantly enhanced relative to naive cells. Whereas nM etorphine moderately shortened the APD of naive DRG neurons (mean decrease to about 86 + 6%; n=18; see Figures 1A and 2), this low concentration was much more effective on
15   chronic morphine-treated DRG neurons (mean decrease to 66% + 7% (n=9)), when tested in the presence of morphine (Figure 4). Dose-response tests of etorphine on chronic DADLE- or morphine-treated DRG neurons showed that the magnitude of the APD was progressively shortened when the acute etorphine
20   concentration was tested sequentially from 1 fM to 1 μM in the presence of μM DADLE or morphine (Figure 4). On the other hand, after washout of the chronic morphine, acute application of etorphine to chronic μM opioid-treated DRG neurons no longer showed greater inhibitory effectiveness as
25   compared to tests on naive cells (n=10) (Figure 4). These

-28-

results suggest that the apparent enhancement in inhibitory effectiveness of etorphine (and dihydroetorphine), when tested during chronic exposure to bimodally-acting opioid-treated DRG neurons, is due to their dual synergistic action as agonists at

5   inhibitory opioid receptors and antagonists at excitatory opioid receptors. The latter property results in unmasking of the inhibitory actions of the chronic DADLE or morphine, as occurs in similar tests on naive neurons (see Figure 1C and Figure 3). Acute application of dihydroetorphine to chronic

10   µM morphine-treated DRG neurons indicated that this opioid showed even greater inhibitory potency than etorphine. fM concentrations shortened the APD in 80% of the treated cells (n=10) and pM (or higher) levels were effective on all cells tested in the presence of the chronic opioid (n=10).

15   Thus, etorphine and dihydroetorphine show similarly remarkable effectiveness as diprenorphine in antagonizing excitatory opioid receptors even when tested in the presence of 10^6-10^9 higher concentrations of morphine or DADLE. As a result of these unusual properties, etorphine and

20   dihydroetorphine showed no cross-tolerance in tests on chronic DADLE- or morphine-treated DRG neurons, just as chronic morphine-treated mice showed no cross-tolerance to etorphine even when the analgesic ED for morphine had increased 15-fold (see Lange et al., Toxicol. Applied Pharmacol., Vol. 54, pp.

25   177-186 (1980)). The absence of cross-tolerance to etorphine

-29-

in chronic morphine-treated DRG neurons is in sharp contrast to
the attenuated inhibitory effects (i.e., ·tolerance) and the
enhanced excitatory effects (i.e., "dependence") displayed by
all bimodally-acting mu, delta and kappa opioid agonists when
tested acutely on these chronic opioid-treated cells.

Example 4

Etorphine Or Dihydroetorphine Can Block Naloxone-Precipitated Supersensitive Excitatory Effects In Chronic Opioid-Treated DRG Neurons

Drug tests: Mouse DRG-cord explants, grown for >3
weeks as described in Example 1, were chronically exposed to
the bimodally-acting (excitatory/inhibitory) delta/mu opioid
agonist, DADLE (1 μM or morphine (1 μM) for 1 week or
longer. The excitatory opioid supersensitivity of chronic
opioid-treated DRG neurons was precipitated by naloxone
(1 nM). Electrophysiological recordings were made as in
Example 1.

Results: The opioid antagonist, naloxone
(1 nM-1 μM) does not alter the APD of naive DRG neurons. In
contrast, after chronic opioid treatment (as well as after
acute GM1 ganglioside treatment) excitatory opioid receptor
functions become so supersensitive that acute application of
low concentrations of naloxone prolonged the APD of the treated
sensory neurons, presumably due to weak partial agonist

-30-

properties of naloxone at excitatory opioid receptors (see
Crain and Shen, Brain Res., Vol. 575, pp. 13-24 (1992) and
Crain and Shen, J. Pharmacol. Exp. Ther., Vol. 260, pp. 182-186
(1992)). Naloxone (1 nM) elicited excitatory APD-prolonging
effects in 92% of the chronic μM DADLE- or morphine-treated
DRG neurons tested in the present study (n=12) (see Figure 5).

These results provide a novel cellular model to
account for naloxone-precipitated withdrawal supersensitivity
in opiate addicts in vivo. It should be emphasized that
naloxone was not simply blocking the inhibitory effect of
residual DADLE or morphine since the treated DRG neurons were
already tolerant to these APD-shortening effects. It is
therefore of great interest that acute application of
remarkably low concentrations of etorphine (fM-nM) to chronic
μM morphine or DADLE-treated cells could effectively block
naloxone-induced APD prolongation in all of the treated DRG
neurons (n=18) (see Figure 5), thereby mimicking the potent
effects of the related etorphine analog dihydroetorphine in
suppressing naloxone-evoked withdrawal symptoms in opiate
addicts (see Wang et al., Chinese J. Pharmacol. Toxicol.,
Vol. 6, pp. 36-40 (1992)).

Figure 5 shows that after chronic exposure to morphine
(Mor) or other bimodally-acting opioids, acute application of
low concentrations of etorphine (Et) can dose-dependently block
the excitatory APD-prolonging effects of naloxone (NLX) on

these supersensitive DRG neurons. Histogram shows that acute
application of 1 nM NLX to DRG neurons chronically treated with
3 μM Mor for 1-4 weeks prolonged the APD by about 50%, tested
in the presence of 3 μM Mor. See also Inset: records 1 and

5   2. In contrast, NLX (nM-μM) does not alter the APD of naive
DRG neurons. Sequential co-perfusions with 1 fM to 1 μM Et
elicit dose-dependent attenuation of the NLX-induced APD
prolongation in these treated neurons, resulting in shortening
of the APD to about 70% of the control value in 1 μM Et. In

10   contrast, NLX-pretreatment of naive DRG neurons blocks
Et-induced APD shortening (see Figure 1B). Inset records 1 and
2 show that 1 nM NLX prolongs the APD of a DRG neuron after
chronic 3 μM Mor treatment for 2 weeks and tested in the
presence of 3 μM Mor (5 minute test). Inset record 3 shows

15   that acute addition of 1 fM Et attenuates the NLX-induced APD
prolongation (5 minute test). Inset record 4 shows that
increasing the concentration of Et to 1 pM almost completely
blocks the NLX-induced APD prolongation. Inset records 5 and 6
show that sequential application of 1 nM and 1 μM Et in the

20   presence of Mor and NLX results in progressive shortening of
the APD well below the initial magnitude in chronic Mor (as
shown in Figure 4).

These results suggest that the potent dose-dependent
effects of etorphine and dihydroetorphine in blocking

25   naloxone-evoked APD prolongation in chronic opioid-treated DRG

-32-

neurons <u>in</u> <u>vitro</u> and withdrawal syndromes in opiate addicts <u>in</u>

<u>vivo</u> is due to the strong antagonist actions of these opioids

at supersensitive excitatory opioid receptors which have become

responsive to the weak agonist properties of naloxone. This is

in sharp contrast to the blockade of etorphine-induced APD

shortening in naive DRG neurons by naloxone under conditions

where it acts primarily as an antagonist at inhibitory opioid

receptors (see Figure 5 and Figure 1B).

<div align="center">

<u>Example 5</u>
</div>

<u>In The Presence Of Etorphine, Chronic Morphine Treatment Of DRG</u>
<u>Neurons No Longer Results In Development Of Opioid Excitatory</u>
<u>Supersensitivity And Tolerance</u>

            <u>Drug tests</u>: Mouse DRG-cord explants, grown for >3

weeks as described in Example 1, were chronically exposed to

bimodally-acting opioid agonist, morphine (1 µM) and opioid

excitatory receptor antagonist, etorphine (1 pM) for >1 week

and tested for opioid excitatory supersensitivity of DRG

neurons at low concentrations of naloxone or dynorphin A (1-13)

and tolerance to the opioid inhibitory effects of APD with high

concentrations of morphine. Electrophysiological recordings

were made as in Example 1.

            <u>Results</u>: Co-administration of low (pM) concentrations

of etorphine during chronic treatment of DRG neurons with µM

levels of morphine was remarkably effective in preventing

<div align="center">

-33-
</div>

development of the opioid excitatory supersensitivity and tolerance that generally occurs after sustained exposure to bimodally-acting opioids. Acute application of 1 fM dynorphin (1-13) (n=10) or 10 nM naloxone (n=8) to DRG neurons chronically exposed to 3 μM morphine together with 1 pM etorphine (for >1 week) did not evoke the usual excitatory APD prolongation observed in chronic morphine-treated cells, even when tested up to 6 hours after return to BSS. Furthermore, there was little or no evidence of tolerance to the inhibitory effects of μM morphine: 6 out of 10 cells still showed APD shortening following acute application of μM morphine similar to tests on naive DRG cells. If etorphine was acting simply as an agonist at inhibitory opioid receptors, one might predict that the addition of 1 pM etorphine together with a 10^6-fold higher concentration of morphine would have a negligible effect on chronic morphine-treated DRG neurons or would augment development of cellular signs of dependence. On the other hand, the results are readily accounted for by the potent antagonist action of etorphine at excitatory opioid receptors during chronic morphine treatment, thereby preventing development of opioid excitatory supersensitivity and tolerance, just as occurs during chronic opioid treatment of DRG neurons in the presence of cholera toxin-B subunit (see Shen and Crain, Brain Res., Vol. 597, pp. 74-83 (1992)). This toxic subunit selectively interferes with GM1 ganglioside

-34-

regulation of excitatory opioid receptor functions (see Shen
and Crain, Brain Res., Vol. 531, pp. 1-7 (1990) and Shen et
al., Brain Res., Vol. 559, pp. 130-138 (1991)).

Example 6

5   Chronic Etorphine-Treated DRG Neurons Do Not Develop Opioid
Excitatory Supersensitivity Or Tolerance

Drug tests: Mouse DRG-cord explants, grown for >3
weeks as described in Example 1, were chronically exposed to
etorphine (nM) for >1 week and tested for opioid excitatory
10   supersensitivity of DRG neurons to low concentrations of
naloxone or dynorphin A (1-13) and tolerance to the inhibitory
effects of higher concentrations of etorphine.

Results: Chronic treatment of DRG neurons with
etorphine alone even at a relatively high concentration (10 nM)
15   for >1 week in culture also did not result in opioid excitatory
supersensitivity when tested acutely with 1 fM dynorphin (1-13)
(26 out of 28 cells) or 1-10 nM naloxone (13 out of 14 cells),
either before or after withdrawal of the chronic etorphine
(Figure 6).

20   Figure 6 shows that after chronic exposure to nM
etorphine (Et), DRG neurons do not become supersensitive to the
excitatory effects of dynorphin 1-13 (Dyn) and naloxone (NLX),
nor do they develop tolerance to the inhibitory effects of
etorphine or other opioid agonists. Record 1 shows the action

25

potential (AP) generated by a DRG neuron after chronic 10 nM Et

treatment for 20 days and tested in balanced salt solution

(BSS) shortly after washout of the Et. Record 2 shows that APD

is not altered by 1 fM Dyn. Records 3-6 show that APD is not

5   altered by bath perfusion with 1 fM Et but is progressively

shortened by 1 pM and 1 μM concentrations (5 minute test

periods). Records 7 and 8 show that APD of the same neuron is

not altered by application of 10 nM NLX. Record 9 shows that

APD is no longer shortened by 1 μM Et when co-perfused with

10   10 nM naloxone (5 minute test period).

After etorphine withdrawal for about 1 hour, 1 nM

dynorphin (1-13) <u>shortened</u> the APD in 3 cells or did not show

typical APD prolongation (10 out of 11 cells), resembling the

attenuation of opioid excitatory effects and unmasking of

15   opioid inhibition observed in acute tests on naive cells after

washout of low (pM) concentrations of etorphine (see

Figure 1C). Furthermore, after washout of the chronic 10 nM

etorphine, acute application of pM, nM and μM etorphine

elicited similar APD shortening (in 3 our of 4 cells tested at

20   each concentration) as observed in naive cells. Thus chronic

10 nM etorphine treatment of DRG neurons did not result in the

characteristic cellular signs of physical dependence and

tolerance that occurred after chronic exposure of these cells

to morphine and other bimodally-acting opioids.

25

Estimates Of Specific In Vivo Dosages Of Excitatory Opioid
Receptor Antagonists That May Enhance Analgesic Potency And
Reduce Dependence Liability (And Other Side-Effects) Of
Morphine Or Other Conventional Opioid Analgesics When
Administered In Combination

Electrophysiological studies on DRG neurons indicated
that pre-treatment with low fM-pM concentrations of etorphine,
dihydroetorphine and diprenorphine are remarkably effective in
blocking excitatory APD-prolonging effects of morphine
bimodally-acting opioid agonists by selective antagonist
actions at mu, delta and kappa excitatory opioid receptors.
The potency of these three excitatory opioid receptor
antagonists is clearly shown by their ability to unmask
inhibitory opioid receptor-mediated APD-shortening effects,
even in the presence of 10^6-fold higher concentrations of
morphine or other bimodally-acting opioid agonists (Figures
3-5).

In the presence of these selective excitatory opioid
receptor antagonists, morphine and other clinically used
opioids showed markedly increased potency in evoking the
inhibitory effects on the action potential of sensory neurons
which are generally considered to underly opioid analgesic
action in vivo. These bimodally-acting opioid agonists became
effective in shortening, instead of prolonging, the APD at
pM-nM (i.e., 10^{-12}-10^{-9} M) concentrations, whereas

-37-

0.1-1 μM   (i.e., 10^{-7}-10^{-6} M)   levels   were   generally
required to shorten the APD (Figure 2). Selective blockade of
the excitatory side-effects of these bimodally-acting opioid
agonists eliminates the attenuation of their inhibitory
effectiveness that would otherwise occur. Hence, according to
this invention, the combined use of a relatively low dose of
one of these selective excitatory opioid receptor antagonists,
together with morphine or other bimodally-acting mu, delta or
kappa opioid agonists, will markedly enhance the analgesic
potency of said opioid agonist, and render said opioid agonist
comparable in potency to etorphine or dihydroetorphine, which,
when used alone at higher doses, are >1000 times more potent
than morphine in eliciting analgesia.

Co-administration of one of these excitatory opioid
receptor antagonists at low concentration (about 10^{-12} M)
during chronic treatment of sensory neurons with 10^{-6} M
morphine or other bimodally-acting opioids (>1 week in culture)
prevented   development   of   the   opioid   excitatory
supersensitivity,   including   naloxone-precipitated
APD-prolongation, as well as the tolerance to opioid inhibitory
effects that generally occurs after chronic opioid exposure.
This experimental paradigm was previously utilized by the
inventors on sensory neurons in culture to demonstrate that
co-administration of 10^{-7} M cholera toxin-B subunit, which
binds selectively to GM1 ganglioside and thereby blocks

-38-

excitatory GM1-regulated opioid receptor-mediated effects, but not opioid inhibitory effects (see Shen and Crain, <u>Brain Res.</u>, Vol. 531, pp. 1-7 (1990)) during chronic opioid treatment prevents development of these plastic changes in neuronal

5   sensitivity that are considered to be cellular manifestations related to opioid dependence/addiction and tolerance <u>in vivo</u> (see Shen and Crain, <u>Brain Res.</u>, Vol. 597, pp. 74-83 (1992)). Hence, according to this invention, the sustained use of a relatively low clinical dose of one of these selective

10   excitatory opioid receptor antagonists, e.g., <1 microgram of etorphine, dihydroetorphine or diprenorphine, <u>in combination with</u> 10-100 micrograms of morphine or other conventional bimodally-acting opioid analgesics will result in analgesia comparable to that elicited by said analgesics when

15   administered alone in milligram doses and will attenuate or even prevent development of physical dependence and other undesirable excitatory side-effects generally associated with said analgesics.

      <u>Estimates Of Specific In Vivo Dosages That Provide Improved</u>

20   <u>Detoxification And Treatment Of Opiate Addicts</u>

             Acute application of one of these excitatory opioid receptor antagonists, e.g., etorphine or dihydroetorphine, at a low concentration (about 10^{-12} M) to chronic opioid-treated sensory neurons prevented the excitatory APD-prolonging effects

25

precipitated by naloxone (10^{-9} M) (Figure 5). The latter

effects provide a novel cellular model to account for

naloxone-evoked withdrawal supersensitivity in opiate addicts

in vivo. The potent effects of etorphine and dihydroetorphine

5   in blocking naloxone-evoked APD prolongation in chronic

opioid-treated sensory neurons in vitro (Figure 5) is due to

their blockade of supersensitive excitatory opioid receptors

which have become responsive to the weak agonist properties of

naloxone. A similar mechanism may account for the efficacy of

10   dihydroetorphine in suppressing naloxone-evoked withdrawal

syndromes in opiate-addicted animals and humans (see Lange,

Toxicol. Applied Pharmacol., Vol. 54, pp. 177-186 (1992) and

Qin, Chinese J. Pharmacol. Toxicol., Vol. 6, (1992)). Hence,

according to this invention, appropriately low doses of one of

15   these selective excitatory opioid receptor antagonists, e.g.,

about 1 microgram in combination with a 10-1000 fold lower than

standard dose of one of the opioids currently used for the

treatment of opioid dependence, e.g., methadone, buprenorphine,

will provide an improved method for detoxifying and weaning

20   addicts from dependence on opiates.

Although the invention herein has been described with

reference to particular embodiments, it is to be understood

that these embodiments are merely illustrative of various

aspects of the invention. Thus, it is to be understood that

25

numerous modifications may be made in the illustrative embodiments and other arrangements may be devised without departing from the spirit and scope of the invention.

WE CLAIM:

1. A method of selectively enhancing the analgesic potency of a bimodally-acting opioid agonist which activates both inhibitory and excitatory receptors on neurons in the nociceptive pathway and simultaneously attenuating undesirable
5   excitatory side-effects caused by said bimodally-acting opioid agonist comprising the co-administration of said bimodally-acting opioid agonist with an opioid receptor antagonist capable of inactivating excitatory but not inhibitory receptors on said neurons.

2. The method of Claim 1 wherein the opioid receptor antagonist is selected from the group consisting of etorphine, dihydroetorphine, diprenorphine, opioid alkaloids and opioid peptides.

3. The method of Claim 1 wherein the bimodally-acting opioid agonist is a conventional opioid analgesic, and is selected from the group consisting of opioid alkaloids, including morphine, codeine and fentanyl analogs,
5   and opioid peptides, including enkephalins, dynorphins and endorphins.

4. The method of Claim 1 wherein the opioid receptor is a mu, delta, kappa or epsilon subtype receptor.

5. The method of Claim 1 wherein the undesirable excitatory side-effect is selected from the group consisting of anti-analgesic effects, physical dependence, tolerance, hyperexcitability and hyperalgesia.

6.   The method of Claim 1 wherein the dose of bimodally-acting opioid agonist to be administered is 10-1000 times less than the amount of that bimodally-acting opioid agonist which is typically administered clinically for analgesia.

7.   The method of Claim 1 wherein the dose of opioid receptor antagonist to be administered is 10-1000 times less than the dose of bimodally-acting opioid agonist administered.

8.   The method of Claim 1 wherein the mode of administration is selected from the group consisting of sublingual, intramuscular, subcutaneous and intraveneous.

9.   A method of detoxifying and treating an opiate addict comprising the co-administration of a bimodally-acting opioid agonist which activates both inhibitory and excitatory receptors on neurons in the nociceptive pathway with an opioid receptor antagonist capable of inactivating excitatory but not inhibitory receptors on said neurons.

10.   The method of Claim 9 wherein the opioid receptor antagonist is selected from the group consisting of etorphine, dihydroetorphine, diprenorphine, opioid alkaloids and opioid peptides.

11.   The method of Claim 9 wherein the bimodally-acting opioid agonist is selected from the group consisting of methadone, buprenorphine and other opioids used for treating opiate addicts.

-43-

12. The method of Claim 9 wherein the opioid receptor is a mu, delta, kappa or epsilon subtype receptor.

13. The method of Claim 9 wherein the dose of bimodally-acting opioid agonist to be administered is 10-1000 times less than the amount of that bimodally-acting opioid agonist which is typically administered clinically for analgesia.

14. The method of Claim 9 wherein the dose of opioid receptor antagonist to be administered is 10-1000 times less than the dose of bimodally-acting opioid agonist administered.

15. The method of Claim 9 wherein the mode of administration is selected from the group consisting of sublingual, intramuscular, subcutaneous and intravenous.

16. A composition comprising a bimodally-acting opioid agonist and an excitatory opioid receptor antagonist.

17. The composition of Claim 16 wherein the excitatory opioid receptor antagonist is selected from the group consisting of etorphine, dihydroetorphine, diprenorphine, opioid alkaloids and opioid peptides.

18. The composition of Claim 16 wherein the bimodally-acting opioid agonist is selected from the group consisting of opioid alkaloids, including morphine, codeine, fentanyl analogs, methadone and buprenorphine, and opioid peptides, including enkephalins, dynorphins and endorphins.

	International application No.
	PCT/US94/08288

A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) :A61K 31/485
US CL :514/282

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 514/282

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Journal of Medicinal Chemistry, Merck Index, Merck Manual

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y,&	US, A, 4,889,860 (Rzeszotarski et al.) 26 December 1989, see entire document, especially Column 5, the Examples, the Claims.	1-18
Y,&	US, A, 4,760,069 (Rzeszotarski et al.) 26 July 1988, see entire document, especially Column 5, the Examples, the Claims.	1-18

☐ Further documents are listed in the continuation of Box C. ☐ See patent family annex.

	Special categories of cited documents:	"T"	later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"A"	document defining the general state of the art which is not considered to be of particular relevance		
"E"	earlier document published on or after the international filing date	"X"	document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"L"	document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)		
"O"	document referring to an oral disclosure, use, exhibition or other means	"Y"	document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"P"	document published prior to the international filing date but later than the priority date claimed	"&"	document member of the same patent family

Date of the actual completion of the international search	Date of mailing of the international search report
27 OCTOBER 1994	07 NOV 1994
Name and mailing address of the ISA/US Commissioner of Patents and Trademarks Box PCT Washington, D.C. 20231	Authorized officer Michael B. Hydorn
